ABSTRACT: This project proposes a new multi-input isolated DC-DC converter for hybrid electric vehicles application. In this work, fuel cell and energy storage system are utilized as the input sources for the proposed system. Fuel is considered as the main power supply. Utilized to charge the battery, increase the efficiency, reduce fuel economy and supplying the output load ,charging and discharging the battery can be made by the FC and pv sources simultaneously or individually. The main advantage of proposed converter is that, the proposed multi input converter has a capability of providing the demanded power by load in absence of one or two resources.

I. INTRODUCTION

Due to increasing diligence on energy crisis and environmental protection, the Hybrid Electric Vehicles (HEVS) are received lot of attention in recent years. Petroleum is used world-wide at a higher rate due to the wider requirement of transport. It plays a major role in modelling the vehicles with minimum and without consumption of petroleum. And therefore the alternate propulsion technologies have been increasingly engaged by the automobile industries and this hassled to the increased exploitation rate of HEV. One of the main advantages for the HEV drive is to improve the efficiency of the motor drive. The key components of the traction systems in hybrid electric vehicles are the multi input bidirectional DC-DC converters. Multi input bidirectional converters have

combine the different sources, such as batteries, ultra capacitor, photovoltaic cells, fuel cells, and other renewable energy sources, with different voltage characteristics. The designs characteristic of the induction motor are used in HEV (1-6), the overview of HEV are discussed. By applying suitable starting frequency and voltage for the inverter fed induction motor low starting current and high starting torque can be obtained (7). Using high frequency transformer to connect different sources, where each source is connected by full-bridge cells using 12 switches for three sources (8). A current fed half-bridge topology has been proposed in [9] to reduce the ripple current in the battery using phase shift modulation. The stability analyses of multiple input isolated buck-boost and forward

converters along have been presented in [10]. In these types of converters, power sharing between various sources is difficult to control. In [11], energy flow between number of different sources and the dc link are discussed. In this topology, it is not possible to transfer energy directly between dc sources, and also, a higher number of devices are being used. In this paper a new type of multi input bidirectional DCDC converter will be proposed in order to integrate various energy sources. The proposed circuit will be analyzed, modelled, designed, controlled, and simulated. Due to the advantages like low cost and compact structure multi input bidirectional DC-DC converter are reported to be designed for HEV application. DC-DC converter is an electrical circuit which provides varying voltage levels that differs from the supplied voltage. DC-DC converter is employed in variety of application. The unregulated DC voltage is given as the input to the DCDC converter. That converter produces the regulated output voltage even though the input voltage is changing.

Due to the fact that initial cost of PVs is high and in order to increase the extracted power from the PV panels, MPPT algorithm has to be utilized. In [22], a general comparison is made between different MPPT techniques with respect to tracking factor, dynamic response, PV voltage ripple, and use of sensors. The other way to improve the efficiency is to enhance the efficiency of the electric components [23].

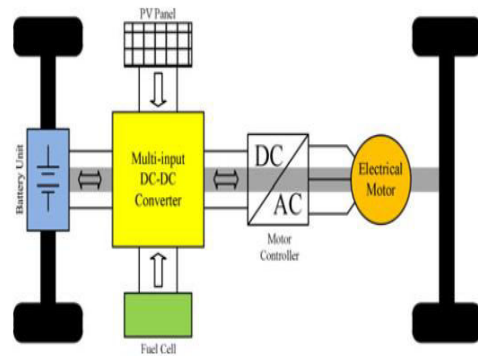

Fig. 1. General structure of the multi powered HEV.

Fig. 2. Three-input dc-dc boost converter. In this study, a novel three-input dc-dc converter is proposed to merge a PV, a fuel cell, and a battery and connect them to the grid. Furthermore, dc gain is enhanced in respect of conventional converters. Meanwhile, MPPT can be obtained for PV. The battery can be charged and discharged in order to achieve power management. In the following two sections, the proposed structure is studied and different operation modes are discussed.

II PROPOSED CONVERTER TOPOLOGY

The structure of the proposed three-input dc-dc boost converter is depicted in Fig. 2.

The converter is formed of two conventional boost converters, substituting extra capacitor in one of the converters, and a battery to store the energy. Characteristic of the converter is suitable for hybrid systems. In this paper, behavior of the converter in terms of managing the sources is analyzed in power management and control part. Then, v_{PV} and v_{FC} are two independent power sources that output is based on characteristic of them. L_1 and L_2 are the inductances of input filters of PV panel and fuel cell. Using L_1 and L_2 as in series with input sources change PV and FC modules to current sources. r_1 and r_2 are v_{PV} 'S and v_{FC} 'S equivalent resistance, respectively. R_{Load} is the equivalent resistance of loads connected to the dc bus. $S_1, S_2, S_3,$ and S_4 are power switches.

Diodes $D_1, D_2, D_3,$ and D_4 are used to establish modes, which will be described. Capacitor C_1 is used to increase output gain and output capacitor C_o is performed as an output voltage filter. System is operating in continuous-conduct mode to produce smooth current with least possible amount of current ripple.

III OPERATION MODES

In this section, principles of the proposed converter are discussed. Operation of the converter is divided into three states:

- 1) The load is supplied by PV and FC and battery is not used.
- 2) The load is supplied by PV, FC, and battery, in this state, battery is in discharging mode.
- 3) The load is supplied by PV and FC and battery is in charging mode.

A First Operation State (the Load is Supplied by PV and FC While Battery is Not Used)

In this state, as it is illustrated in Fig. 3, there are three operation modes. During this state, the system is operating without battery charging or discharging. Therefore, there are two paths for current to flow (through S_3 and D_3 or D_1 and S_4). In this paper, S_3 and D_3 is considered as common path. However, D_1 and S_4 could be chosen as an alternative path. During this state, switch S_3 is permanently ON and switch S_4 is OFF.

Mode 1: ($0 < t < d_1T$): In this interval, switches $S_1, S_2, S_3,$ and diode D_3 are turned ON. Inductors L_1 and L_2 are charged via power sources V_{PV} and V_{FC} , respectively [see Fig. 3(a)].

Mode 2: ($d_1T < t < d_2T$): In this interval, switch S_1 is turned OFF and D_2 is turned ON and $S_2, S_3,$ and D_3 are still ON. Inductor L_2 is still charged and inductor L_1 is being discharged via $V_{FC} - V_{C_1}$ [see Fig. 3(b)].

Mode 3: ($d_2T < t < T$): In this interval, S_1 is turned ON and S_2 is turned OFF and S_3 and D_3 are still ON. Inductor L_1 is charged with V_{PV} and inductor L_2 is discharged via $V_{PV} + V_{C_1} - V_o$ [see Fig. 3(c)].

By applying the voltage-second balance law over the inductors L_1 and L_2 , voltage of capacitor C_1 and output voltage can be obtained as follows:

$$L_1 : d_1 [V_{PV} - r_1 i_{L_1}] + (d_2 - d_1) [V_{PV} - r_1 i_{L_1} - V_{C_1}] + (1 - d_2) [V_{PV} - r_1 i_{L_1}] = 0 \quad (1)$$

$$V_{C_1} = \frac{V_{PV} - r_1 i_{L_1}}{d_2 - d_1} \quad (2)$$

$$L_2 : d_2 [V_{FC} - r_2 i_{L_2}] + (1 - d_2) [V_{FC} + V_{C_1} - r_2 i_{L_2} - V_o] \quad (3)$$

$$i_{batt} = 0$$

$$V_o = \frac{(d_2 - d_1)(V_{FC} - r_2 i_{L_2}) + (1 - d_2)(V_{FC} - r_1 i_{L_1})}{(1 - d_2)(d_2 - d_1)} \quad (4)$$

$$P_{batt} = 0.$$

B. Second Operation State (the Load is Supplied by PV, FC, and Battery)

In this state, as it is illustrated in Fig. 4, there are four operation modes. During this state, the load is supplied by all input sources (PV, FC, and battery). In first mode, there is only one current path. However, in other three modes, there are two current paths (through S3 and D3 or D1 and S4). In this state, current flows through D1 and S4. Switch S4 is permanently ON during this state.

Fig. 4.3. Current-flow path of operating modes in first operating state. (a) Mode 1. (b) Mode 2. (c) Mode 3.

Also, by applying the current-second balance law over the capacitors C1 and Co, voltage of capacitor C1, we have

$$C_1 : (d_2 - d_1) i_{L_1} - (1 - d_2) i_{L_2} = 0 \quad (5)$$

$$C_o : (1 - d_2) i_{L_2} = \frac{V_o}{R_{Load}} \quad (6)$$

In this case, battery is not used and so we have

Mode 1: ($0 < t < d_1 T$): In this interval, S1, S2, S3, and S4 are turned ON. Inductors L1 and L2 are charged by $V_{PV} + v_{Battery}$ and $V_{FC} + v_{Battery}$, respectively [see Fig. 4(a)].

Mode 2: ($d_1 T < t < d_2 T$): In this interval, S1, S2, S4, and D1 are turned ON. Inductors L1 and L2 are charged by V_{PV} and V_{FC} , respectively [see Fig. 4(b)].

Mode 3: ($d_2 T < t < d_3 T$): In this interval, S2, S4, D1, and D2 are turned ON. Inductor L1 is discharged to capacitor C1 and L2 is charged by v_{FC} [see Fig. 4(c)].

Mode 4: ($d_3 T < t < d_4 T$): In this interval, S1, S4, D1, and D4 are turned ON. Inductor L1 is charged by V_{PV} and inductor L2 discharges C1 to the output capacitor [see Fig. 4(d)].

By applying the voltage-second balance law over the inductors L1 and L2, we have

$$L_1 : d_1 [V_{PV} + V_{batt} - r_1 i_{L_1}] + (d_2 - d_1) [V_{PV} - r_1 i_{L_1}] + (d_3 - d_2) [V_{PV} - r_1 i_{L_1} - V_{C_1}] + (1 - d_3) [V_{PV} - r_1 i_{L_1}] = 0 \quad (8)$$

And then

$$V_{C1} = \frac{V_{PV} + d_1 V_{batt} - r_1 i_{L1}}{d_3 - d_2} \times L_2 : d_1 [V_{FC} + V_{batt} - r_2 i_{L2}] + (d_3 - d_1) [V_{FC} - r_2 i_{L2}] + (1 - d_3) [V_{FC} + V_{C1} - r_2 i_{L2} - V_o] = 0. \quad (9)$$

$$V_o = \frac{(d_3 - d_2) (V_{FC} + d_1 V_{batt} - r_2 i_{L2}) + (1 - d_3) (V_{PV} + d_1 V_{batt} - r_1 i_{L1})}{(1 - d_3) (d_3 - d_2)} \quad (4.10)$$

Also, by applying the current-second balance law over the capacitors C1 and Co, voltage of capacitor C1, we have

$$C_1 : (d_3 - d_2) i_{L1} - (1 - d_3) i_{L2} = 0 \quad (4.11)$$

$$C_o : (1 - d_3) i_{L2} = \frac{V_o}{R_{Load}} \quad (4.12)$$

In this state, the current and power of battery can be calculated as (4.13) and (4.14), respectively

$$i_{batt} = d_1 (i_{L2} + i_{L1}) \quad (4.13)$$

$$P_{batt} = V_{batt} [d_1 (i_{L2} + i_{L1})] \quad (4.14)$$

C. Third Operation State (the Load is Supplied by PV and FC While Battery is in Charging Mode)

In this state, as it is illustrated in Fig. 5, there are four modes. During this state, PV and FC charges the battery and supply the energy of load.

Fig. .4. Current-flow paths in different operation modes of second state. (a) Mode 1. (b) Mode 2. (c) Mode 3. (d) Mode 4.

Fig. 5. Current-flow path of operating modes in third operating state. (a) Mode 1. (b) Mode 2. (c) Mode 3. (d) Mode 4.

In the first- and second-operation modes, there are two possible current paths through S3 and D3 or D1 and S4). The path D1 and S4 is chosen to flow the current in this state. During this state,

switch S3 is permanently OFF and diode D1 conducts.

Mode 1: ($0 < t < d_1T$): In this interval, S1, S2, S4, and D1 are turned ON. Inductors L1 and L2 are charged by vPV and vF C , respectively [see Fig. 4.5(a)].

Mode 2: ($d_1T < t < d_2T$): In this interval, S2, S4, and D1 are turned ON. Inductor L1 is discharged to capacitor C1 and inductor L2 is charged by vF C [see Fig. 4.5(b)].

Mode 3: ($d_2T < t < d_3T$): In this interval, S1, S2, D1, and D3 are turned ON. Inductors L1 and L2 are charged by vPV – vBattery and vF C – vBattery , respectively [see Fig. 4.5(c)].

Mode 4: ($d_3T < t < d_4T$): In this interval, S1, S4, D1, and D4 are turned ON. Inductor L1 is charged by vPV – vBattery and inductor L2 is discharged by vF C – vC1 – vo[see Fig. 4.5(d)].

By applying the voltage–second balance low over the inductors L1 and L2, we have

$$L_1 : d_1 [V_{PV} - r_1 i_{L_1}] + (d_2 - d_1) [V_{PV} - r_1 i_{L_1} - V_{C_1}] + (1 - d_2) [V_{PV} - r_1 i_{L_1} - V_{batt}] = 0 \quad (15)$$

$$V_{C_1} = \frac{V_{PV} - (1 - d_2) V_{batt} - r_1 i_{L_1}}{d_2 - d_1} \quad (16)$$

$$L_2 : d_2 [V_{FC} - r_2 i_{L_2}] + (d_3 - d_2) [V_{FC} - r_2 i_{L_2} - V_{batt}] + (1 - d_3) [V_{FC} + V_{C_1} - r_2 i_{L_2} - V_o] = 0 \quad (17)$$

$$V_o = \frac{(V_{FC} - (d_3 - d_2) V_{batt} - r_2 i_{L_2})}{(1 - d_3)} + \frac{(V_{PV} - (1 - d_2) V_{batt} - r_1 i_{L_1})}{(d_2 - d_1)} \quad (18)$$

By applying current–second balance low to capacitors C1 and Co, we have

$$C_1 : (d_2 - d_1) i_{L_1} - (1 - d_3) i_{L_2} = 0 \quad (19)$$

$$C_o : (1 - d_3) i_{L_2} = \frac{V_o}{R_{Load}} \quad (20)$$

In this state, the current and delivered power by battery can be obtained as (4.21) and (4.22)

$$i_{batt} = (d_3 - d_2) (i_{L_2} + i_{L_1}) + (1 - d_3) i_{L_1} \quad (21)$$

$$P_{batt} = V_{batt} [(d_3 - d_2) (i_{L_2} + i_{L_1}) + (1 - d_3) i_{L_1}] \quad (22)$$

Fig.6 illustrates switching pattern for each state and each mode. To fulfill switching operation, a saw-tooth wave as a carrier is compared with signals d1, d2, d3, and d4, which can independently control on state of power switches. Without considering output voltage utilized power of each sources PV, FC, and battery can be controlled using d1, d2, d3, and d4 signals. The voltage gain of the proposed converter is compared with the converter proposed. As shown in this figure, the voltage gain of the proposed converter is higher than the converter proposed in [24]. Benefiting from high-voltage gain, the proposed converter achieve the specific output voltage VO with less duty cycles in comparison with the converter proposed in [24] which increase the efficiency of the

proposed converter. It is worth noting that in this figure, the inductor resistances are ignored and the voltage gain is compared in the first operation mode. Input voltages are also considered the same.

IV. DYNAMIC MODELING AND CONTROL

In order to control and analyze dynamic performance of the proposed converter, it should be modeled. As it has been mentioned, the presented converter operates in three states that first state is made of three modes and second and third states are contained of four modes. Each state operates to provide particular goals, which will be explained. In first state, output voltage and only one of the input power sources can be controlled. Due to this fact in this paper, we decide to control PV power source, which can be replaced by FC source as well. In second state because of interference the battery, output voltages and input sources power rate can be controlled. Third states' control parameters due to interference the battery is same as second state.

As mentioned previously interference the battery consists of two states, which in one of them battery will be charged and in one of them battery will be discharged. Selection of proper state (without battery, battery charging, battery discharging) is depends on power managing algorithm. Dynamic model of the proposed converter for each state is as follows.

First state: In this state, d_1 and d_2 as control variables, control output voltage, and power rate of one of the input sources that is consider PV in this paper. State-space model of converter for first state is

$$L_1 \frac{di_{L1}}{dt} = V_{PV} + (d_1 - d_2)V_{C1} - r_1 i_{L1} \quad (23)$$

$$L_2 \frac{di_{L2}}{dt} = V_{FC} + (1 - d_2)V_{C1} + (d_2 - 1)V_o - r_2 i_{L2} \quad (24)$$

$$C_o \frac{dV_o}{dt} = (1 - d_2) i_{L2} - \frac{V_o}{R_{Load}} \quad (25)$$

$$C_1 \frac{dV_{C1}}{dt} = (d_2 - d_1) i_{L1} - (1 - d_2) i_{L2}. \quad (26)$$

Second state: In this state, three control variables d_1 , d_2 , and d_3 are used for controlling three state variables. In this state, the state-space model of converter is

$$L_1 \frac{di_{L1}}{dt} = V_{PV} + d_1 V_{batt} + (d_2 - d_3)V_{C1} - r_1 i_{L1} \quad (27)$$

$$L_2 \frac{di_{L2}}{dt} = V_{FC} + d_1 V_{batt} + (1 - d_3)V_{C1} + (d_3 - 1)V_o - r_2 i_{L2} \quad (28)$$

$$C_o \frac{dV_o}{dt} = (1 - d_3) i_{L2} - \frac{V_o}{R_{Load}} \quad (29)$$

$$C_1 \frac{dV_{C1}}{dt} = (d_3 - d_2) i_{L1} - (1 - d_3) i_{L2}. \quad (30)$$

Third state: In this state, same as second state, three state variables are controlled by three control variables d_1 , d_2 , and d_3 controlling. State-space model of the converter in this state can be written as follows:

$$L_1 \frac{di_{L1}}{dt} = V_{PV} + (d_2 - 1)V_{batt} + (d_1 - d_2)V_{C1} - r_1 i_{L1} \quad (31)$$

$$L_2 \frac{di_{L2}}{dt} = V_{FC} + (d_2 - d_3)V_{batt} + (1 - d_3)V_{C1} + (d_3 - 1)V_o - r_2 i_{L2} \quad (32)$$

$$C_o \frac{dV_o}{dt} = (1 - d_3) i_{L2} - \frac{V_o}{R_{Load}} \quad (33)$$

$$C_1 \frac{dV_{C1}}{dt} = (d_2 - d_1) i_{L1} - (1 - d_3) i_{L2} \quad (34)$$

V CONCLUSION

The multi input bidirectional DC-DC converter was designed to integrate more than two DC sources with different voltage levels which finds application in HEV. The multi input bidirectional converter can control the power flow between each pair of sources. The required voltage to drive a three phase induction motor is obtained by photo voltaic cells and multi input bidirectional DC-DC converter. MPPT control technique is used to extract the maximum power from solar irradiation. Instead of using individual converter in hybrid system using multi input bidirectional DC-DC converter is reduces the system size and cost. Therefore proposed converter provides the better efficiency but harmonics presents in voltage source. The performance of the

system has been verified by simulation using MATLAB/SIMULINK environment.
